Thiol

ABSTRACT

Objectives: To develop a novel and automated assay determining plasma thiol/disulphide homeostasis, which consists of thiol–disulphide exchanges.

Design and methods: Native thiol and total thiol concentrations were synchronously measured as a paired test. In the first vessel, the amount of native thiol groups was measured by a modified Ellman reagent. At the parallel run, first, dynamic disulphide bonds were reduced to free thiol groups by NaBH4. The unused reductant remnants were completely removed by formaldehyde. Thus, the total thiol amount could be accurately measured. Mercaptotoethanol solutions were used as calibrators. The half value of the difference between total thiol and native thiol amounts gave the disulphide bond amount.

Results: No separation step for the assay was needed. All processes were performed using an automated analyser within about 10 min. Plasma disulphide levels were 17.29 ± 5.32 μmol/L, native thiol levels were 397 ± 62 μmol/L and disulphide/native thiol per cent ratios were 4.32 ± 1.49 in healthy subjects. Plasma disulphide levels were higher in patients with degenerative diseases and lower in patients with proliferative diseases.

Conclusion: An easy, inexpensive, practical, fully automated and also optionally manual spectrophotometric assay can be used to determine plasma dynamic thiol/disulphide homeostasis.

Introduction

Thiols, also known as mercaptans, are a class of organic compounds that contain a sulfhydryl group (–SH) composed of a sulphur atom and a hydrogen atom attached to a carbon atom [1]. The plasma thiol pool is mainly formed by albumin thiols, protein thiols and slightly formed by low-molecular-weight thiols such as cysteine (Cys), cysteinylglycine, glutathione, homocysteine and γ-glutamylcysteine [2].

Thiols (RSH) can undergo oxidation reaction via oxidants and form disulphide (RSSR) bonds [3]. A disulphide bond is a covalent bond; the linkage is also called a SS-bond or disulphide bridge. Under conditions of oxidative stress, the oxidation of Cys residues can lead to the reversible formation of mixed disulphides between protein thiol groups and low-molecular-mass thiols. The formed disulphide bonds can again be reduced to thiol groups; thus, dynamic thiol–disulphide homeostasis is maintained [4].

Dynamic thiol disulphide homeostasis status has critical roles in antioxidant protection, detoxification, signal transduction, apoptosis, regulation of enzymatic activity and transcription factors and cellular signalling mechanisms [5,6]. Moreover, dynamic thiol disulphide homeostasis is being increasingly implicated in many disorders. There is also a growing body of evidence demonstrating that an abnormal thiol disulphide homeostasis state is involved in the pathogenesis of a variety of diseases, including diabetes [7], cardiovascular disease [8], cancer [9], rheumatoid arthritis [10], chronic kidney disease [11], acquired immunodeficiency syndrome (AIDS) [12], Parkinson’s disease, Alzheimer’s disease, Friedreich’s ataxia (FRDA), multiple sclerosis and amyotrophic lateral sclerosis [13–15] and liver disorder [16]. Therefore, determination of dynamic thiol disulphide homeostasis can provide valuable information on various normal or abnormal biochemical processes.

The plasma thiol level is most commonly measured using the classical Ellman reagent, 5,5′-dithiobis-(2-nitrobenzoic) acid (DTNB). This compound is stoichiometrically reduced by free thiols in an exchange reaction, forming a mixed disulphide and releasing one molecule of 5-thionitrobenzoic acid, which can be measured at 412 nm [17]. An alternative reagent to DTNB is 4,4′-dithiodipyridine (4-DPS) [18]. Reduction of 4-DPS leads to 4-thiopyridone tautomer, and this can be measured at 324 nm, which is a near ultraviolet wavelength. This wavelength cannot be used by automated analysers because the lowest wavelength is 340 nm in all automated analysers used in clinical chemistry laboratories.

Abbreviations: NaBH4, sodium borohydrate; DTNB, 5,5′-dithiobis-2-nitrobenzoic acid; GSH, reduced glutathione; GSSG, oxidised glutathione; –SH, RSH, sulfhydryl group; RSSR, –S–S–, disulphide bonds; Cys, cysteine; CySS, cystine; 4-DPS, 4,4′-dithiodipyridine; TCEP, Tris(2-carboxyethyl) phosphine.

To the best of our knowledge, there is no automated colourimetric measurement method for plasma/serum dynamic disulphide levels [19]. In a few recent studies, the disulphide and thiol levels of low-molecular-weight disulphide compounds of plasma have been determined using high-performance liquid chromatography (HPLC) [20,21], fluorescence capillary electrophoresis [22] and bioluminescent systems [23]. In these sophisticated systems, separation processes such as the removal of the remaining reductants, which are NaBH₄, Tris(2-carboxyethyl)phosphine (TCEP) and tributhylphosphine, as well as precipitation of proteins, are also needed [19]. These pretreatment applications and measurement procedures are time-consuming, labour-intensive and costly, and require complicated techniques.

In this study, a novel and automated assay determining dynamic thiol/disulphide homeostasis is described and a new test cluster concept containing −S−S−, −SH, −S−S−−SH, −S−S−/(−SH + −S−S−) and −SH/(−SH + −S−S−) is introduced.

Materials and methods
Chemicals
Reduced glutathione (GSH), oxidised glutathione (GSSG), albumin, 2-mercaptoethanol, 5,5’-dithiobis-2-nitrobenzoic acid (DTNB), hydrogen peroxide (H₂O₂), chloramine-T, ethylenediaminetetraacetic acid (EDTA), NaBH₄, Tris, NaOH, methanol and formaldehyde were purchased from Sigma-Aldrich Chemical Co. (Milwaukee, WI) and Merck (Darmstadt, Germany). All chemicals were ultrapure grade, and type I reagent-grade deionised water was used.

Samples
The new assay can be applied to a wide range of complex biological fluids, including plasma, serum, semen plasma, cerebrospinal, pleural and ascite fluids, urine, haemolysate and simple and heterogeneous solutions of pure chemicals.

Plasma samples
Venous blood samples were collected in tubes containing EDTA. Plasma samples were separated from cells by centrifugation at 1500 × g for 10 min. The samples were run immediately or stored at −80 °C. The study was approved by the Research Ethics Committee.

Apparatus
A Shimadzu UV-1800 spectrophotometer with a temperature controlled cuvette holder and a Cobas c501 automated analyser (Roche) were used.

Assays
The new assay
Principle of the new assay. Dynamic disulphide bonds (−S−S−) in the sample are reduced to functional thiol groups (−SH) by NaBH₄. The unused NaBH₄ remnants are completely removed by formaldehyde. Thus, this prevents the extra reduction of the DTNB and further reduction of the formed disulphide bond, which are produced after the DTNB reaction. The total thiol content of the sample is measured using modified Ellman reagent. Native thiol content is subtracted from the total thiol content and half of the obtained difference gives the disulphide bond amount.

Assay reagents. The assay included two parallel vessels. Three reagents were used in the individual vessels. The first reagents of the vessels were different, while the others were the same reagents. One vessel measured total thiol content, consisting of native thiol plus reduced thiol, and the other measured only the native thiol content of the sample.

Reagent 1 (for total −SH). Reagent 1 (R1) was prepared by dissolving 378 mg of sodium borohydride in 1000 mL of water–methanol solution (50 v/v). The final concentration of sodium borohydride was 10.0 mM. The reagent was prepared freshly and used daily. This reductant solution was used to determine the total thiol content.

Reagent 1′ (for native −SH). Reagent 1′ was prepared by dissolving 585 mg of sodium chloride in 1000 mL of water–methanol solution (50 v/v). The final concentration of sodium chloride was 10.0 mM. This reagent is stable for at least 6 months at 4 °C. The solution was used to determine the native thiol content.

Reagent 2 (and 2′). R2 (2′) was prepared by dissolving 0.5 mL of formaldehyde (final concentration: 6.715 mM) and 3.8 g of EDTA (final concentration: 10.0 mM) in 1000 mL TRIS buffer, 100 mM and pH 8.2. This reagent is stable for at least 6 months at 4 °C. It was used for both of the vessels.

Reagent 3 (and 3′). R3 (3′) was prepared by dissolving 3.963 g of DTNB in 1000 mL of methanol. The final concentration of DTNB was 10.0 mM. The reagent was prepared freshly and used daily. It was used for both of the vessels.

Automated measurements of total/native thiol concentrations and disulphide amounts
After manual spectrophotometric optimisation studies, parallel tests were applied using an automated analyser (Cobas c501, Roche). The assay formats for total and native thiol tests are given below.

The disulphide parameter is a value which can be calculated automatically as half of the difference of the two measured values.

The assays can also be performed by manually using spectrophotometers or multiwell readers. All volumes of the samples and reagents must be increased at the same ratio. Use of a second (side) wavelength in the assay is optional.

Monitoring of thiol–disulphide exchanges
Native thiol, total thiol and disulphide amounts were measured in various pure chemical solutions and biological materials containing sulphhydryl groups. Reduced glutathione, 2-mercaptoethanol and albumin solutions were oxidised with hydrogen peroxide solutions at increasing concentrations (from 0 to 300 μM) for 10 min. Chloramine-T was used as oxidant instead of hydrogen peroxide for the oxidation of thiol groups of plasma, because it contains catalase, which has a high turnover number for hydrogen peroxide. Native thiol, total thiol and disulphide concentrations of the pretreated samples were then determined.
Statistical analyses

The paired Student’s t test, variance analysis, correlation analyses and linear regression analyses were performed using IBM SPSS Statistics (Version 20) computer program (IBM, USA, 2011). Deming regression analyses and difference analyses were performed using the MedCalc (Version 12.7) computer program (MedCalc Software, Belgium, 2013).

Results

Optimisations of NaBH₄ and formaldehyde concentrations

Pure sodium borohydrate solution reduced DTNB to TNB and led to false positive results in the assay. It also reduced the formed disulphide bonds, which are produced after DTNB reduction to TNB, to free sulphydryl groups; this vicious circle proceeded until NaBH₄ was consumed. After the reduction of dynamic disulphide bonds to free sulhydryl groups, the unused NaBH₄ remnants were completely removed using formaldehyde. After the removal of NaBH₄ by formaldehyde, no false positive result interference was seen; thus, the extra reduction of DTNB and further reduction of the formed disulphide bonds were completely prevented. Optimal NaBH₄ concentration was found to be 10 mM. The lower concentrations showed insufficient reduction capacity for disulphide bonds, while the higher concentrations showed false positive results. Optimal concentrations of the chemicals used were determined by changing the concentration of one chemical while the concentrations of the other chemicals were kept constant. The optimal formaldehyde concentration was found to be a mmolar concentration of 6.715.

Modification of Ellman’s reagent

The classical Ellman reagent was modified by adding formaldehyde solution. Addition of the formaldehyde was not interfered with the assay (Fig. 1A). There was an important correlation ($r = 0.99$, $p < 0.001$; $n = 185$) between the results (Fig. 1B). There was no difference between the results of the original and the modified Ellman reagents (Fig. 1C). Thus, the modified Ellman reagent can be confidently used instead of the classical Ellman reagent to determine the sulphydryl group.

Reaction kinetics of blank and various plasma samples

The reaction kinetics of deionised water (as a blank) and plasma pool samples from healthy individuals, which were carried out in the automated analyser, are given in Fig. 2.

Monitoring of thiol–disulphide exchanges of 2-mercaptoethanol

A 500 µM 2-mercaptoethanol solution was prepared; equal and separate portions of the solution were obtained, then they were oxidised with H₂O₂ solution at serially increasing concentrations. Oxidation–reduction reactions were monitored up to 300 µM oxidant concentrations. As seen in Fig. 3A, the linear decrease in native thiol concentrations correlated with the linearly increasing oxidant concentrations ($r = 0.99$, $p < 0.001$). While thiol concentration decreased, disulphide amounts increased in a correlated fashion; no change was observed in the total thiol levels.

Monitoring of thiol–disulphide exchanges of glutathione

A 480 µM GSH solution was prepared; equal and separate portions of the solution were obtained and then oxidised with H₂O₂ solution with serially increasing concentrations. Oxidation–reduction reactions were monitored up to 300 µM oxidant concentrations. As seen in Fig. 3B, the linear decrease in native thiol concentrations correlated with the linearly increasing oxidant concentrations ($r = 0.99$, $p < 0.001$). While thiol concentration decreased, disulphide amounts increased in a correlated fashion; no change was observed in the total thiol levels.

Monitoring of thiol–disulphide exchanges of albumin

A 430 µM albumin solution was prepared; equal and separate portions of the solution were obtained, then oxidised with H₂O₂ solution of serially increasing concentrations. Oxidation–reduction reactions were monitored up to 300 µM oxidant concentrations. As seen in Fig. 4A, the linear decrease in native thiol concentrations correlated with the linearly increasing oxidant concentrations ($r = 0.99$, $p < 0.001$). While the thiol concentration decreased, disulphide amounts increased in a correlated fashion; no change was observed in the total thiol levels.

Monitoring of thiol–disulphide exchanges of plasma samples

A plasma pool was prepared; equal and separate portions of the solution were obtained and then oxidised with chloramine-T solution of serially increasing concentrations. Oxidation–reduction reactions were monitored up to 300 µM oxidant concentrations. As seen in Fig. 4B, the linear decrease in native thiol concentrations correlated with the linearly increasing oxidant concentrations ($r = 0.99$, $p < 0.001$). While thiol concentration decreased, disulphide amounts increased in a correlated fashion; no change was observed in the total thiol levels.
Analytical recovery

The per cent recovery of the novel method was determined via the addition of 200 μM oxidised glutathione to plasma samples. The mean percent recovery was 98–101%.

Linearity

The linearity of the native thiol measurement was the same with that of Ellman’s reagent assay. Serial dilutions of the glutathione solution were generated. The upper limit of the linearity for the native thiol measurement was 4000 μM. Linearity of the total thiol measurement was also dependent on the amounts of NaBH₄ and formaldehyde concentrations. Serial dilutions of the oxidised glutathione solution were also generated. The upper limit of the linearity for the disulphide measurement was 2000 μM. Dilution of plasma samples did not affect the novel assay.

Lower detection limit

The detection limit of the assay was determined by evaluating the zero calibrator 10 times. The detection limit, defined as the mean value of zero calibrator + 3 standard deviations (SDs), was 2.8 μM.

Analytical sensitivity

As the slope of the calibration line, analytical sensitivity was found to be $7.9 \times 10^{-4}$ Absorbance/Amount, $[A \times (μM)^{-1}]$.

there was no published manual or automated method for the measurement of plasma dynamic thiol disulphide status [19]. In this study, thiol disulphide homeostasis was determined by measuring mainly native thiol and reducible dynamic disulphide amounts. Other related parameters were generated by calculations.

In previous advanced experimental studies, disulphide bonds were reduced to thiol groups using TCEP [20], tributylphosphine [22] and NaBH₄ [21]. However, the remaining reductants hampered the measurements. For this reason, the remaining reductants must be absolutely removed before the measurement. Different techniques have been used to remove reductant remnants, such as filtration, chromatography and dialysis, but none of these are appropriate for fully automated measurement. Glowacki et al. [20] used a dialysis system, Carru et al. [22] precipitated proteins via 5-sulphosalicylic acid and Chen et al. [21] acidified the reaction medium to remove the remaining NaBH₄. The dialysis system and precipitation of proteins cannot be applied to automated analysers. On the other hand, acidification of the medium leads to abundant gas and bubble formation, which prevents spectrophotometric measurement and inhibits colour formation of DTNB because the acid medium leads to decolourisation of the formed 5-thio-2-nitrobenzoic acid [18].

In the novel method, the remained, unused reductant NaBH₄ was completely consumed and removed using formaldehyde solution. Moreover, there was no gas and bubble formation, and thus, no light scattering and no light transmission instability were observed in the spectrophotometric measurements. On the other hand, it was shown that the used formaldehyde did not interfere with the measurements (Fig. 1A). There was no significant difference between the original Ellman reagent and the modified reagent results (Fig. 1C). As seen in Fig. 1B, the correlation coefficient was also excellent ($r = 0.99$ and

**Discussion**

Thiol chemistry is a rapidly growing field in basic and applied bioscience, but there has been no report evaluating plasma dynamic thiol disulphide homeostasis. All of the published reports are experimental, manual, sophisticated studies, and they generally relate to the determination of thiol and disulphide compounds such as Cys, CySS, GSG and GSSG [20–23]. Moreover, there is no published manual or automated method for the measurement of plasma dynamic thiol disulphide status [19]. In this study, thiol disulphide homeostasis was determined by measuring mainly native thiol and reducible dynamic disulphide amounts. Other related parameters were generated by calculations.

Interference

It was found that haemoglobin, EDTA, citrate and oxalate did not interfere with the assay developed, but bilirubin did negatively interfere with the assay. Lipaemic and uraemic plasma samples did not interfere with the assay. Plasma and serum samples can be used as samples.

**Precision**

To determine the precision of the novel assay, we assayed three levels of a plasma pool. A plasma pool that had high disulphide levels was obtained from the samples of patients with diabetes mellitus. The plasma pool with medium disulphide levels was obtained from the samples of healthy persons. The plasma pool with low disulphide levels was obtained from the samples of patients with urinary bladder cancer. Per cent coefficient variation (%CV) was 4 ($X = 29.12$ and $\sigma_X = 1.2$) for high levels, 5 ($X = 16.03$ and $\sigma_X = 0.79$) for medium levels and 13 ($X = 7.15$ and $\sigma_X = 0.98$) for low levels.

**Storage**

Storage at 4 °C for 1 day led to a 7% decrease in the native thiol amount and 170% increase in the disulphide amount (total thiol, native thiol and disulphide levels of fresh and stored plasma samples were 391 μmol/L, 357 μmol/L, 17 μmol/L and 391 μmol/L, 333 μmol/L and 29 μmol/L, respectively). Plasma native thiol, total thiol and disulphide concentrations were not affected by storage at −80 °C for 3 months.

**Comparison of plasma and serum thiol and disulphide amounts**

There were no significant differences between native thiol, total thiol and disulphide levels of plasma and serum sample pairs ($p > 0.05$).

**Reference interval**

To determine the reference interval for plasma disulphide levels, plasma specimens from 120 healthy individuals (60 women, 60 men, 16–64 years old) were assayed. The reference range was 6.65–27.93 μmol/L. Plasma disulphide levels were higher in patients with degenerative diseases such as inflammation, smoking, diabetes and obesity, and were lower in patients with neoplastic diseases such as renal cancer, colon cancer, urinary bladder cancer and multiple myeloma.

**Fig. 4.** A: the changes of native thiol, total thiol and disulphide concentrations of albumin solution by increasing the oxidant, hydrogen peroxide. B: the changes of native thiol, total thiol and disulphide concentrations of the plasma pool by increasing the oxidant, chloramine-T.
levels were higher in patients with degenerative diseases such as smoking, diabetes, obesity and pneumonia, and were lower in patients with proliferative diseases such as multiple myeloma, urinary bladder cancer, colon cancer and renal cancer. Aggressively growing tumours showed the lowest disulphide levels, while slowly growing ones showed subnormal values. In previously performed studies, only GSH/GSSG and Cys/CySS redox parameters have been determined at the cellular level. In our study, plasma dynamic thiol/disulphide homeostasis was determined totally by using an automated method.

Conclusions

Plasma dynamic thiol/disulphide homeostasis can be fully automated, as determined by the described assay. In this study, plasma disulphide levels showed different, original and interesting patterns for various disease spectra. The developed assay has high and wide usage potential in research studies and clinical biochemistry laboratories, and has high potential to generate new knowledge and concepts.
